Decoupled and Aggregated Forecasting

Data Pre-processing

Forecasting Track— Quantile Forecast (Wind)

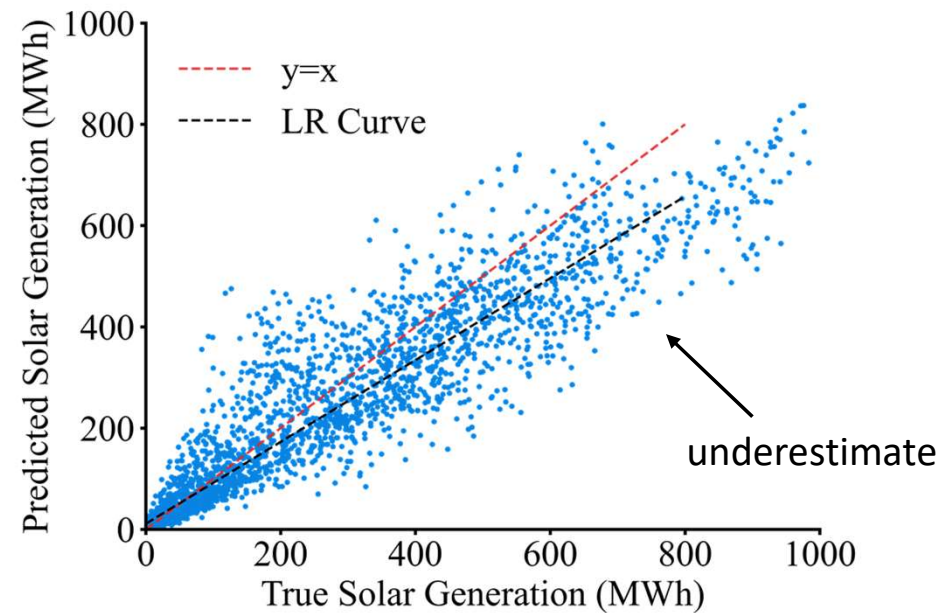

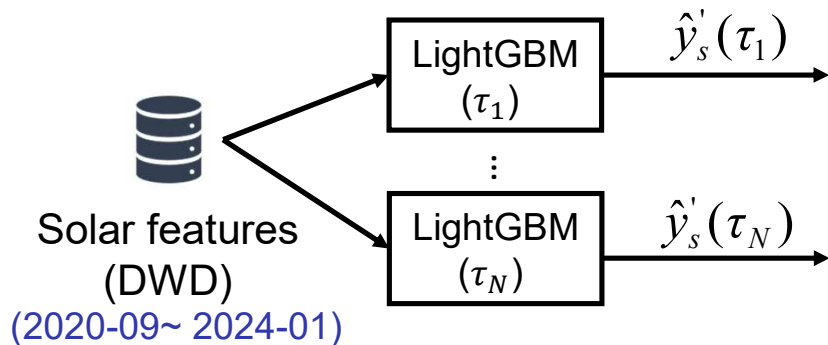

Forecasting Track— Quantile Forecast (Solar)

- Solar capacity changes after the start of HEFTcom

2609 MWp  **2741** MWp (since 2024-02-19)

- Our original framework

Forecasting Track— Quantile Forecast (Solar)

- We consider a polynomial post-processing model:

$$\hat{y}_s(\tau_i) = \beta_1 \hat{y}'_s(\tau_i) + \beta_2 \hat{y}'^2_s(\tau_i) + \beta_3 \hat{y}'^3_s(\tau_i) \quad i=1, \dots, N$$

Final forecast from model trained on historical data

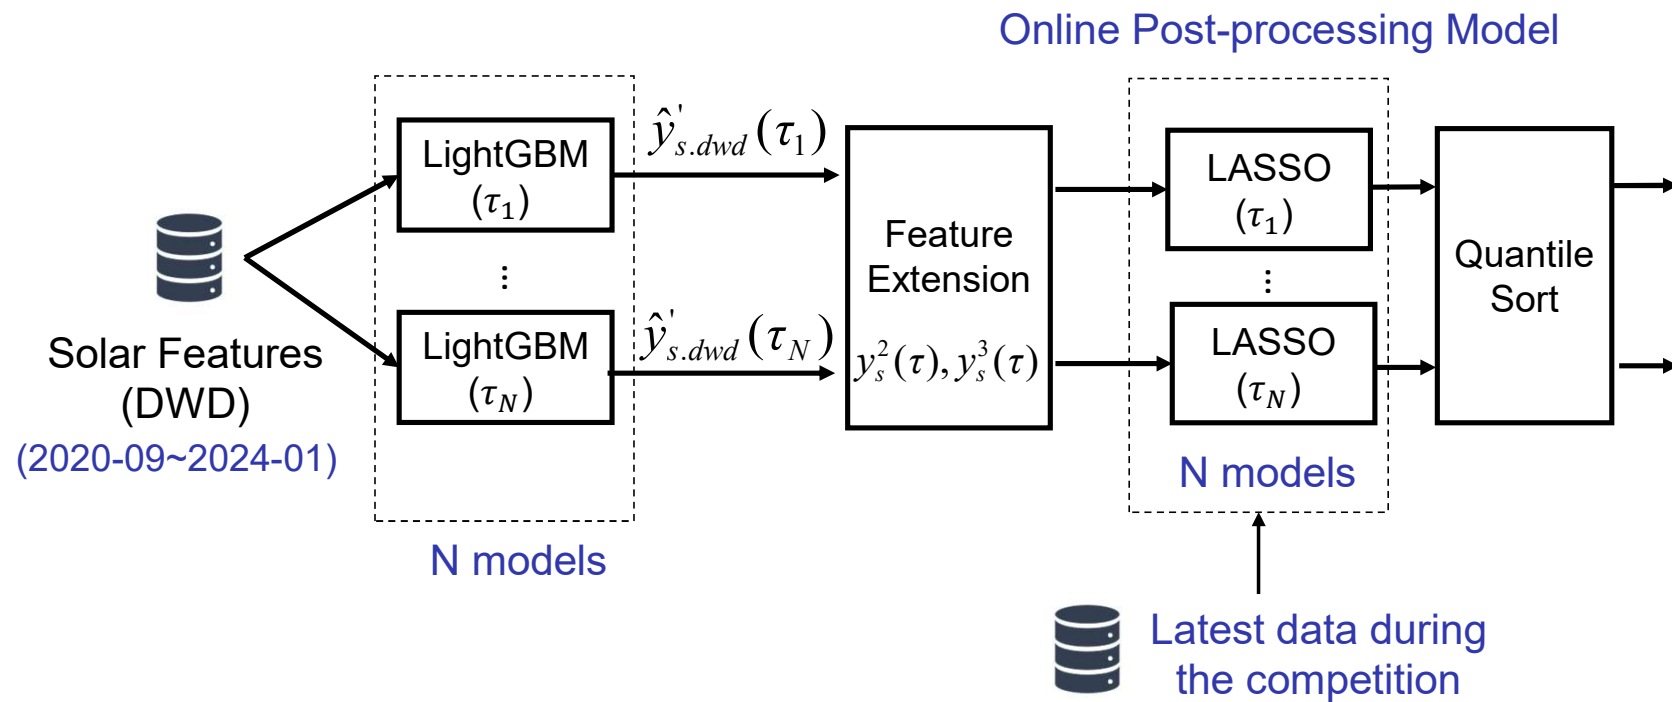

- Using **LASSO quantile regression** to post-process the forecasts from the model trained on historical data

$$\min_{\beta} L_{\tau_i}(y_s, \hat{y}_s) = \tau_i (y_s - \hat{y}_s)^+ + (1 - \tau_i)(\hat{y}_s - y_s)^+ + \lambda \sum_{j=1}^3 |\beta_j| \quad i=1, \dots, N$$

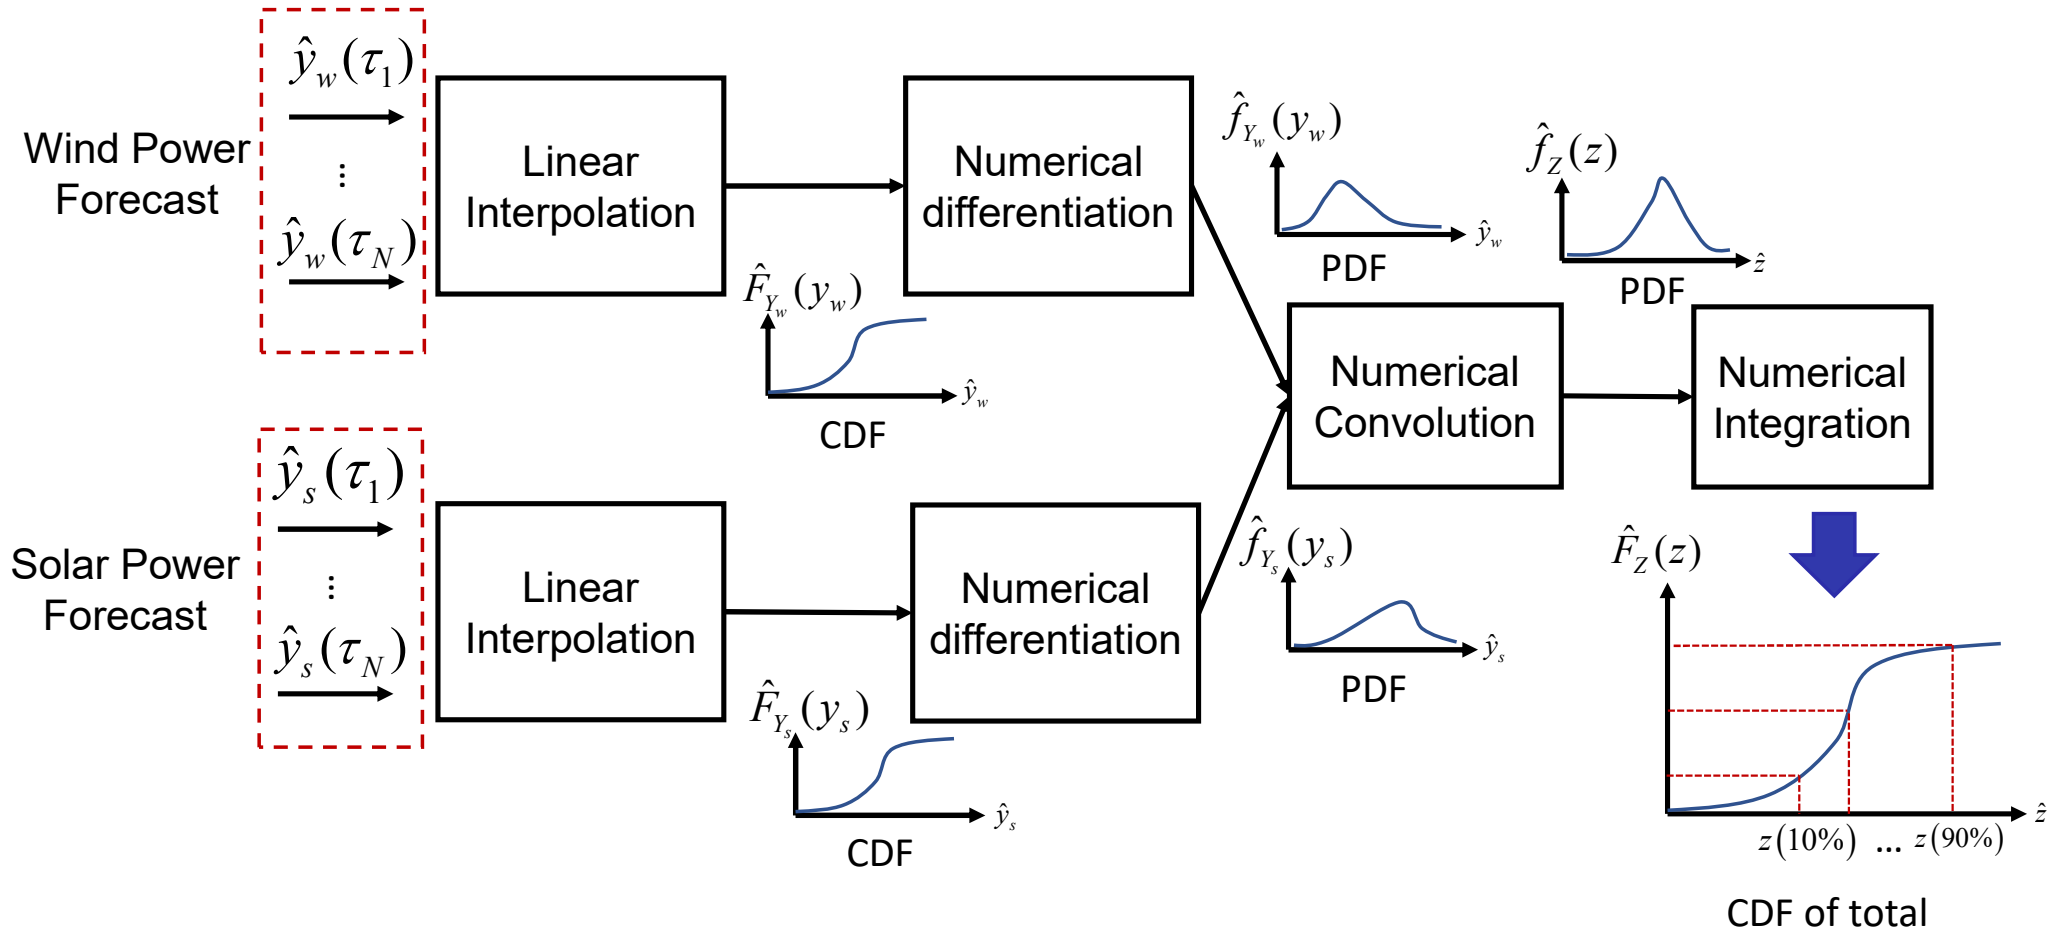

Actual generation after 2024-02-19 L1-regularization to make β sparser

Forecasting Track—Quantile Forecast (Solar)

■ Revised framework:

Forecasting Track—Quantile Aggregation

Forecasting Track— Hyperparameter Tunning

- Optuna Framework
- Search q50 wind and solar model only

```
def objective(trial,X,y,quantile):  
    params_grid={  
        'num_leaves': trial.suggest_int('num_leaves', 100, 1000,step=100),  
        'n_estimators': trial.suggest_categorical("n_estimators", [500,1000,2000]),  
        'max_depth': trial.suggest_int('max_depth', 3, 12),  
        'min_data_in_leaf': trial.suggest_int('min_data_in_leaf', 200, 10000,step=100),  
        'learning_rate': trial.suggest_float('learning_rate', 0.01, 0.3),  
        'lambda_l1': trial.suggest_int('lambda_l1', 0, 100,step=10),  
        'lambda_l2': trial.suggest_int('lambda_l2', 0, 100,step=10),  
        "random_state": 2048,  
        'verbose':-1,  
        'objective':'quantile ',  
        'alpha':quantile/100  
    }
```

Trading Track— Rules

- The revenue:

$$F(\hat{z}_b) = \underbrace{\pi_{da} \hat{z}_b}_{\text{Day-ahead market revenue}} + \underbrace{\pi_{ss} (z - \hat{z}_b)}_{\text{Imbalance revenue}} - \underbrace{0.07(z - \hat{z}_b)^2}_{\text{Penalty of generation deviation}}$$

- We define the price difference:

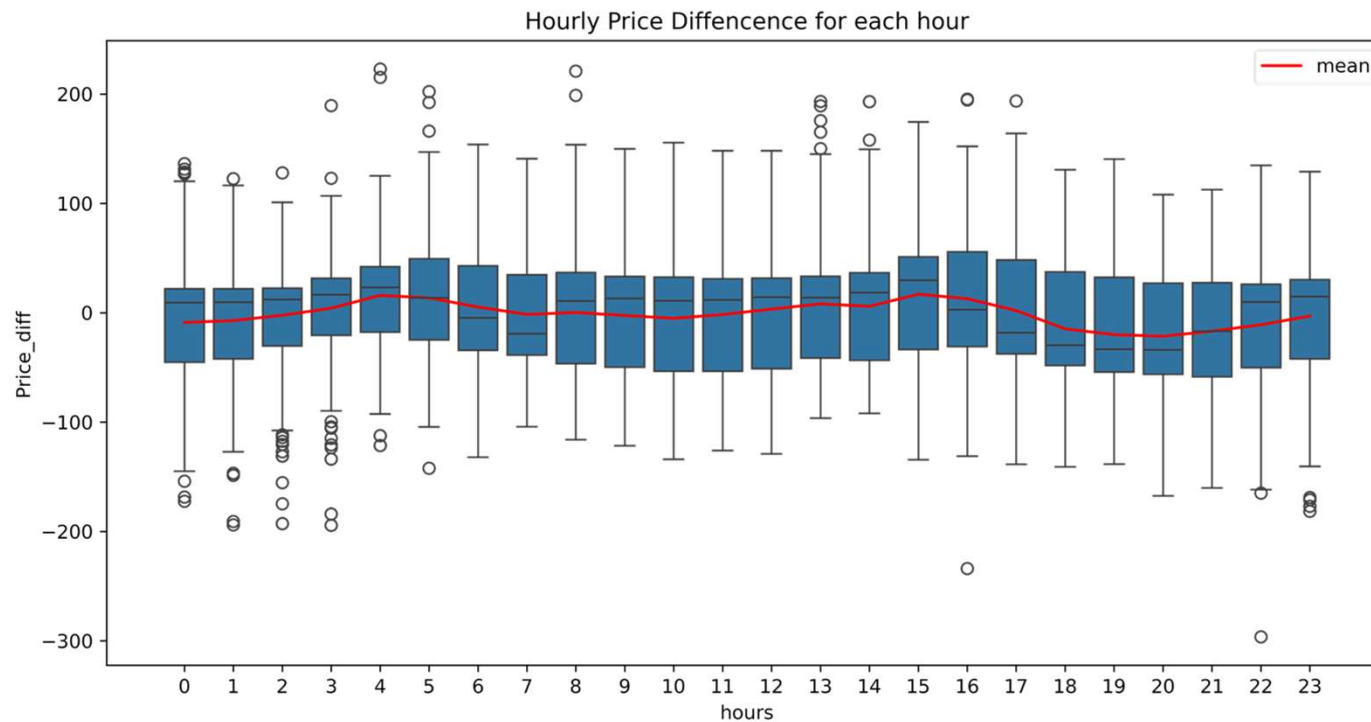

$$\pi_{da} - \pi_{ss} \triangleq \pi_d$$

$$F(\hat{z}_b) = \underbrace{\pi_{ss} z}_{\text{constant}} + \underbrace{\pi_d \hat{z}_b - 0.07(z - \hat{z}_b)^2}_{\text{Needs to maximize}}$$

Notation

π_{da}	Day-ahead price
π_{ss}	Balancing price
z	Actual generation
\hat{z}_b	Bidding volume (decision variable)

Trading Track— Difficulty of Price Forecast

Why price forecasting is difficult ?

- Price difference updates are delayed by 4-5 days
- Lack of global information about the market
- Very high variance caused by power imbalance

What can we find?

- Statistically, the price difference is related to the **hour of day**.

Trading Track— Stochastic Trading

- Probabilistic modeling of uncertain price difference with hour t as a covariate
- We optimize the expectations of trading revenue:

$$\begin{aligned}
 \max J_t(\hat{z}_b) &= \sum_{s \in \Omega} p_s(\pi_{d.s} | t) [\pi_{d,s} \hat{z}_b - 0.07(\hat{z} - \hat{z}_b)^2] \\
 &= \sum_{s \in \Omega} p_s(\pi_{d.s} | t) \pi_{d,s} \hat{z}_b - 0.07(\hat{z} - \hat{z}_b)^2 \sum_{s \in \Omega} p_s(\pi_{d.s} | t) \\
 &= \bar{\pi}_{d,t} \hat{z}_b - 0.07(\hat{z} - \hat{z}_b)^2
 \end{aligned}$$

- The optimal solution is:

$$\hat{z}_{b,t} = \begin{cases} 0 & \hat{z} + 7.14\bar{\pi}_{d,t} \leq 0 \\ 1800 & \hat{z} + 7.14\bar{\pi}_{d,t} \geq 1800 \\ \hat{z} + 7.14\bar{\pi}_{d,t} & \text{others} \end{cases}$$

Rolling average of price differentials over the past two months

power forecast

Trading Track— Decision Loss

- Considering the optimal decision:

$$\hat{z}_b^* = \hat{z} + 7.14\hat{\pi}_d \quad (\text{in most cases})$$

- The actual revenue under actual generation and price difference:

$$F(\hat{z}_b^*) = \pi_d \hat{z}_b^* - 0.07(z - \hat{z}_b^*)^2 + \pi_{ss} z$$

- The theoretical optimal revenue (if forecast=actual):

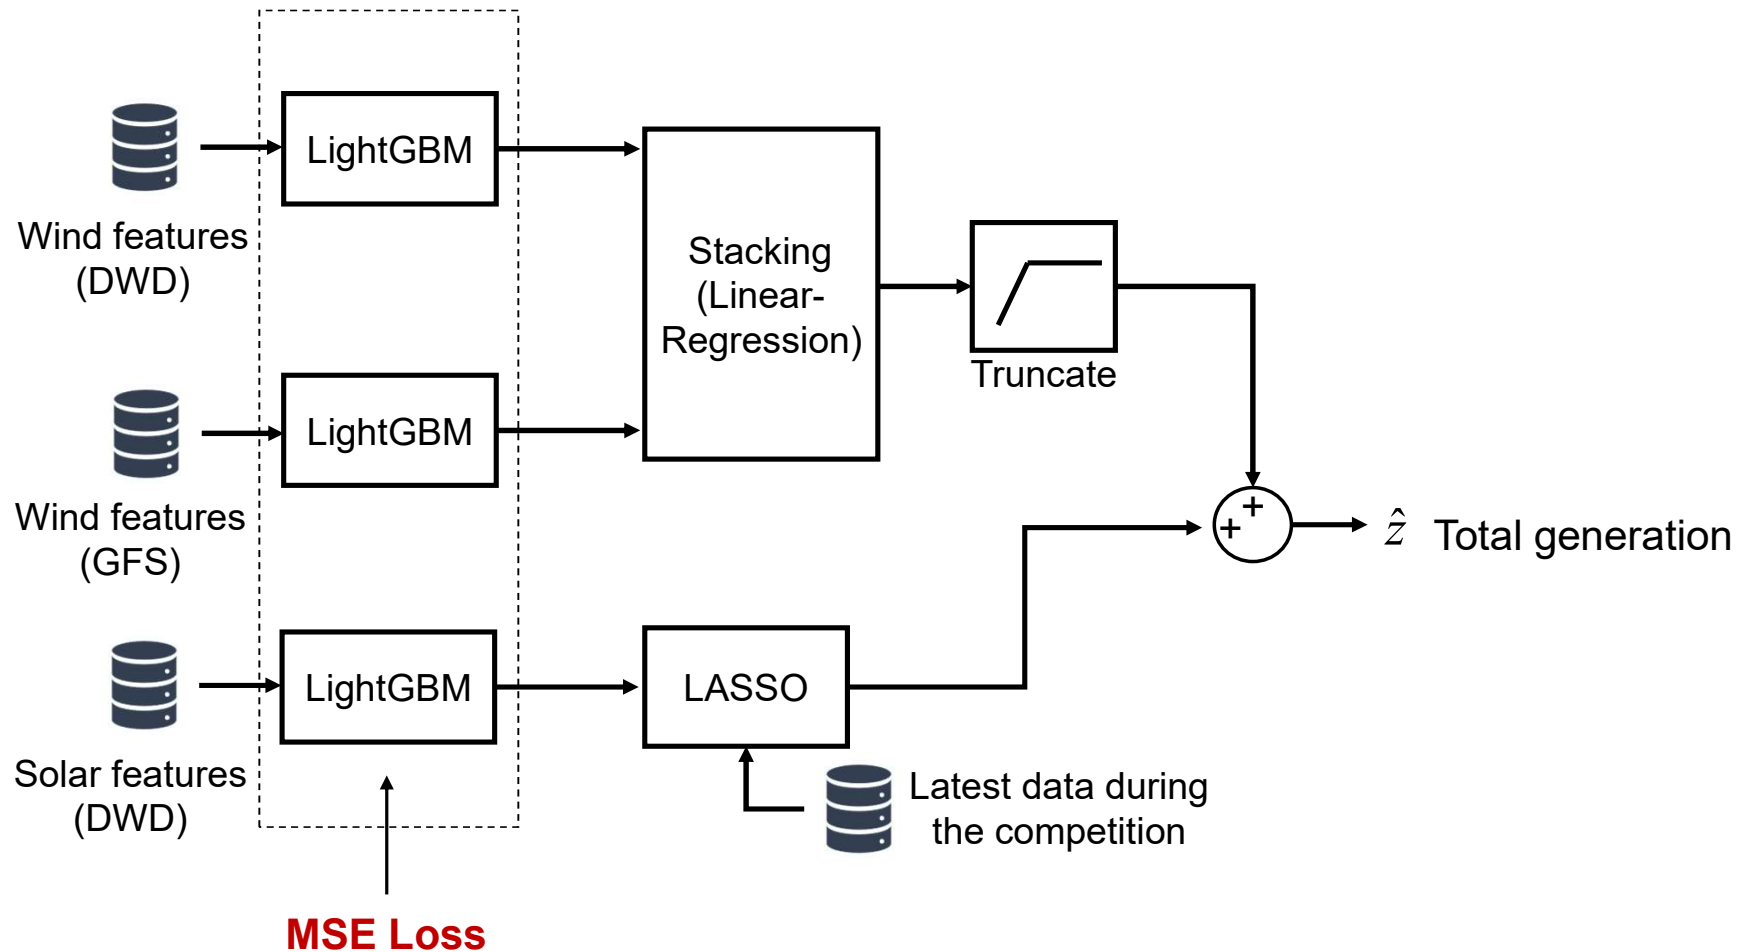

$$F(z_b^*) = \pi_d z_b^* - 0.07(z - z_b^*)^2 + \pi_{ss} z$$

$$\text{where } z_b^* = z + 7.14\pi_d$$

- The gap between the actual revenue and the theoretical optimal revenue is

$$\underbrace{F(z_b^*) - F(\hat{z}_b^*)}_{\text{Decision loss}} = 0.07 \underbrace{(z - \hat{z})^2}_{\text{MSE}} + 3.57 \underbrace{(\pi_d - \hat{\pi}_d)^2}_{\text{MSE}} + \underbrace{(z - \hat{z})(\pi_d - \hat{\pi}_d)}_{\text{Coupled term}}$$

Trading Track— Point Power Forecasting for Trading

Key Approaches to The Specific Challenge of HEFTCom

- **Stacking models with different NWP**

Motivation: To reduce the variance in wind power forecasting

- **Aggregated Quantile Forecasting**

Motivation: Theoretically optimal aggregated method

- **Online Solar Post-processing model**

Motivation: Increased solar capacity without enough new data

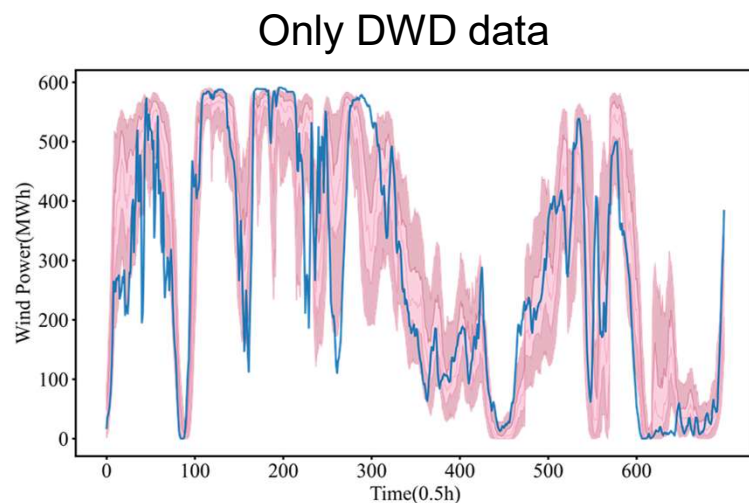

- **Stochastic Trading Strategy**

Motivation: To improve the trading revenue considering the uncertainty of price difference; prices is hard to predicted but statistically related to time series features; we can optimize the long-term expectation

Summary: Effective Approaches

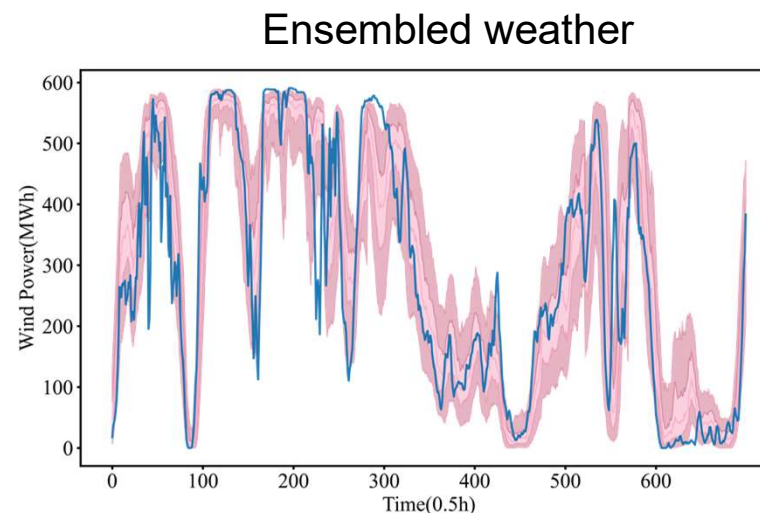

■ Stacking models with different NWP

- Test period: 2023-02-01~2023-08-01, $\text{ref_time}=00:00$, $23 \leq \text{valid_time-ref_time} \leq 48$
- Training dataset: exclude test period

(Partly data displayed)

Mean pinball loss (all quantiles):
28.97

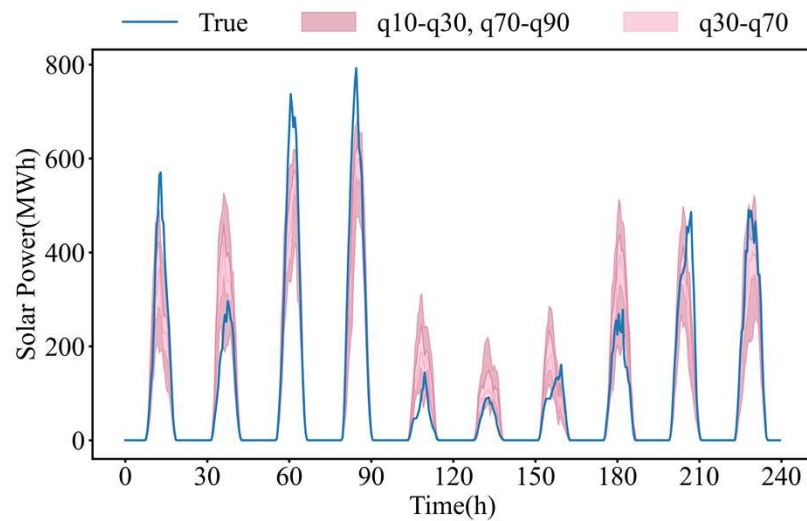

(Partly data displayed)

Mean pinball loss (all quantiles):
27.13

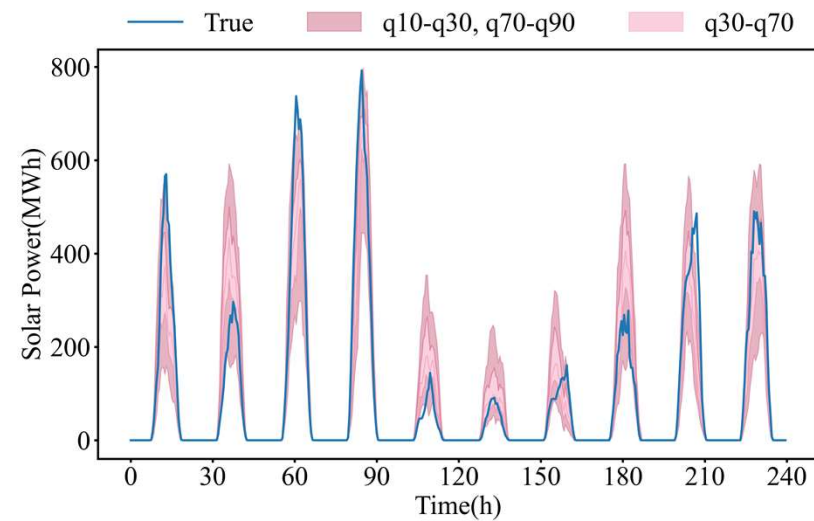

Summary: Effective Approaches

■ Online Post-processing Model

- Latest solar data: 2024-02~2024-05 (dwd only)
- Training set : testing set = 6:4 (random split)

Mean pinball loss: 15.25

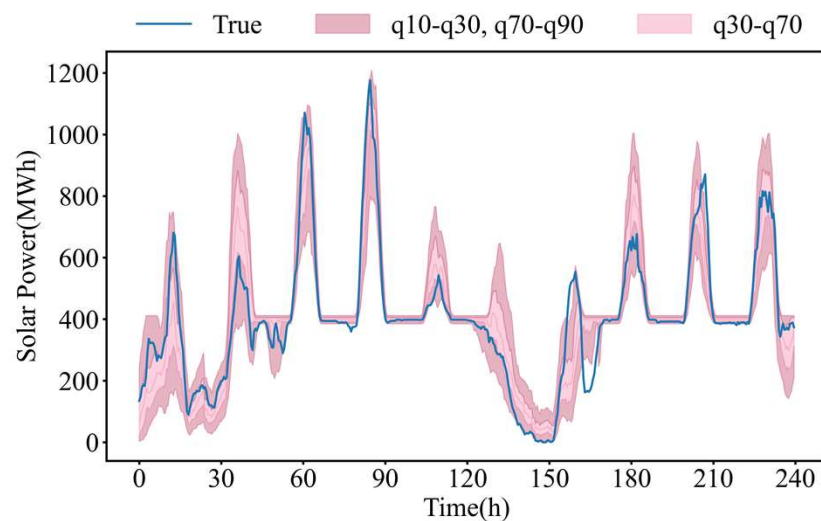

Mean pinball loss: **13.62**

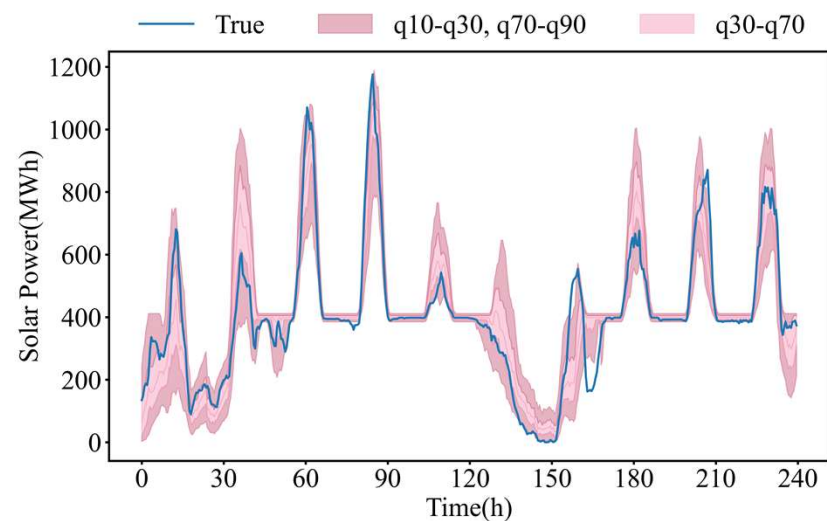

Summary: Effective Approaches

■ Quantile Aggregation

- Test period: 2024-02-020~2024-05-19, ref_time=00:00, $23 \leq \text{valid_time-ref_time} \leq 48$
- Training dataset: exclude test period

Mean pinball loss: 24.41

Mean pinball loss: **24.21**

Summary: Effective Approaches

■ Stochastic Trading

- Test period: 2023-02-01~2023-08-01, ref_time=00:00, $23 \leq \text{valid_time} - \text{ref_time} \leq 48$
- Training dataset: exclude test period

Results

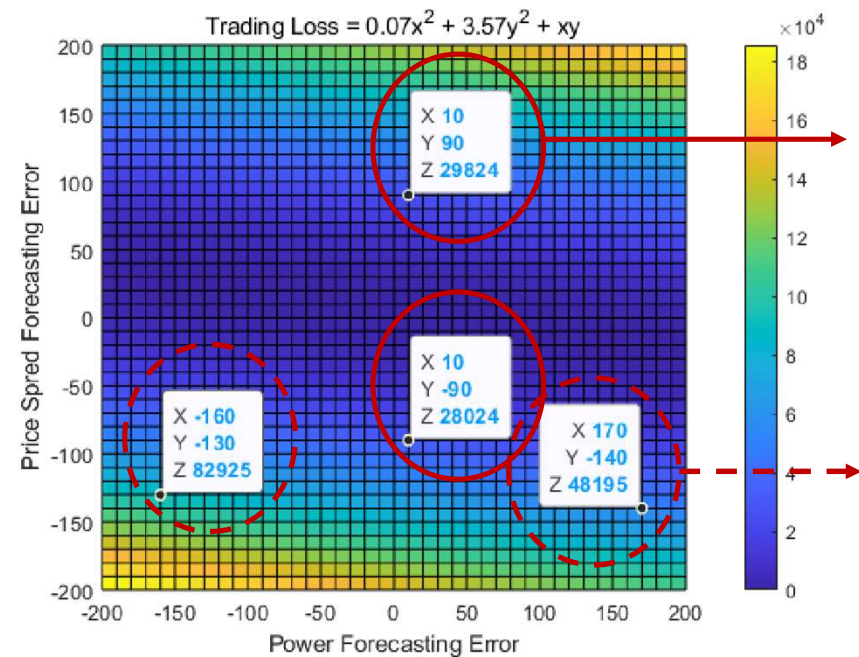

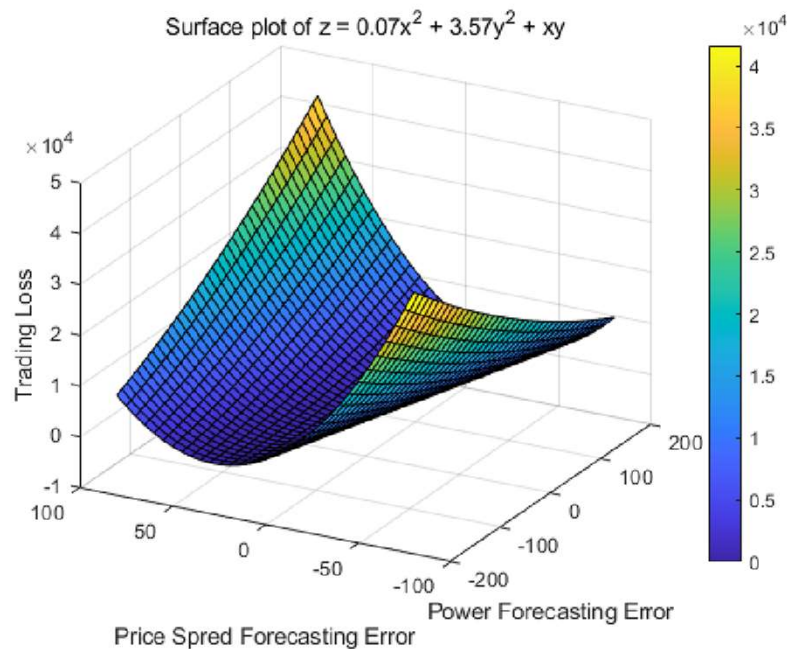

Methods	MAE	RMSE	Mean Daily Revenue (EUR)	Improvement
$\hat{z}_b^* = \hat{z}(q50)$	87.0	130.4	1711694.5	/
$\hat{z}_b^* = \hat{z}(MSE)$	89.0	128.6	1713914.7	0.13%
$\hat{z}_{b,t}^* = \hat{z}_t(q50) + 7.14\bar{\pi}_{d,t}$	/	/	1718821.93	0.42%
$\hat{z}_{b,t}^* = \hat{z}_t(MSE) + 7.14\bar{\pi}_{d,t}$	/	/	1719510.84	0.46%

Our Further Work

- The decision loss

$$F(z_b^*) - F(\hat{z}_b^*) = 0.07(z - \hat{z})^2 + 3.57(\pi_d - \hat{\pi}_d)^2 + (z - \hat{z})(\pi_d - \hat{\pi}_d)$$

- Asymmetric impact of forecast errors on downstream revenue

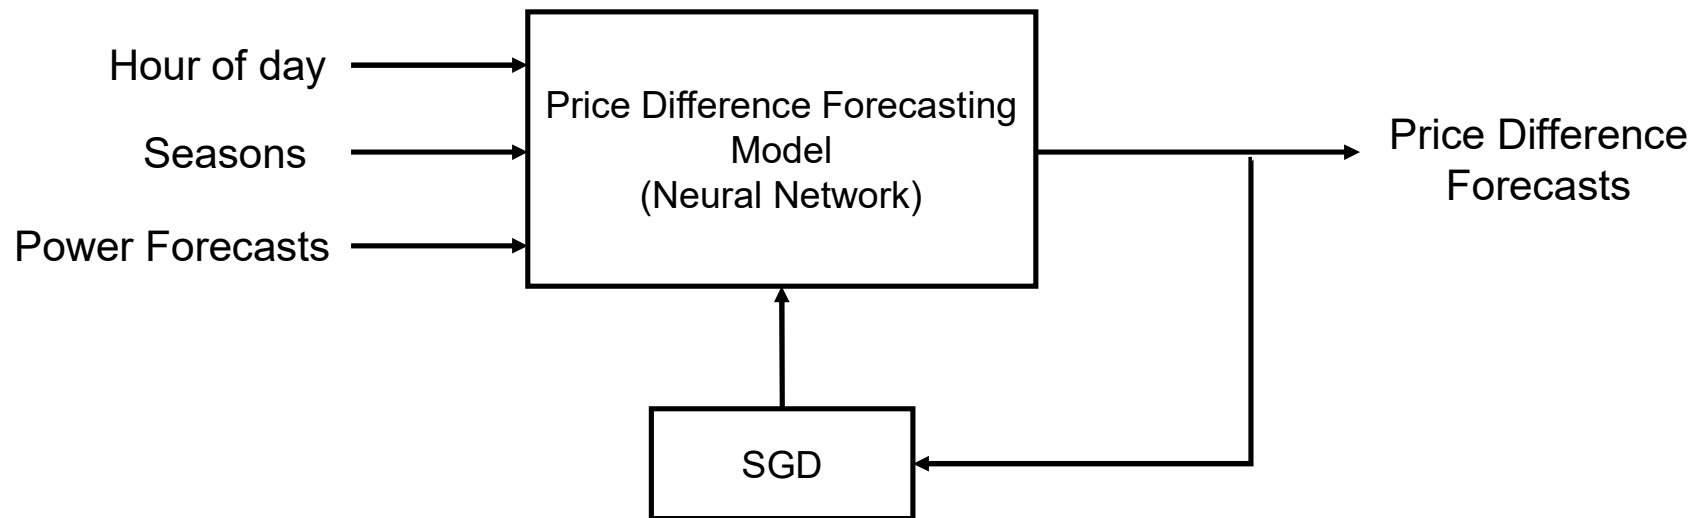

- Same accuracy may lead to different revenue

- high accuracy may lead to high revenue loss

Our Further Work

■ 1. Value-oriented Forecasting

$$\text{minimize } F(z_b^*) - F(\hat{z}_b^*) = 0.07(z - \hat{z})^2 + 3.57(\pi_d - \hat{\pi}_d)^2 + (z - \hat{z})(\pi_d - \hat{\pi}_d)$$

■ 2. Trading with deterministic price difference and power forecasts
